FORWARD DEPLOYED ENGINEER ASSIGNMENT

MoveInSync

Play Store Rating Analysis

Understanding user complaints and prioritising product improvements

Submitted by	Role	Date	Focus
Aprajita Deep	FDE Intern → FTE	October 2026	Public review analysis

Purpose

This report reviews publicly visible feedback about MoveInSync's employee commute app and turns the main reported pain points into a practical improvement plan. The goal is not to assume that every negative review reflects a confirmed software defect, but to identify issues worth validating with product, support and engineering data.

At a glance

Observed signal	What it may indicate	Recommended response
Employee app: 4.6/5 and about 115K reviews in the captured Play Store view	The overall score is strong, but individual high-impact failures can still frustrate employees.	Track recent reviews and issue themes, not only the lifetime average.
Lower ratings shown for related driver/workplace apps observed during research	Different user groups may face different parts of the commute workflow.	Analyse each app separately before drawing conclusions about shared causes.
Public comments mention login, booking clarity and pickup/check-in concerns	Reliability at time-critical steps may have an outsized effect on user trust.	Validate the reports, then fix the highest-risk confirmed issues first.

Important note: ratings can vary by locale, account, app listing state or capture time. The 4.6/5 figure above is recorded from the Play Store screenshot used for this assignment on 10 October 2026; it should be treated as the observed value in that capture, not as a guarantee that every viewer sees the same rating.

1. Current State — What the Numbers Tell Us

A star rating is a useful first signal, but it does not explain the experience behind it. A lifetime average can remain high even when a recent release introduces friction for a subset of users. For a commute app, a login or booking problem can have a larger practical impact than a cosmetic issue because the employee may be trying to reach work on time.

Listing / source	Snapshot observed during research	How to interpret it
MoveInSync employee app	4.6/5; approximately 1L reviews; 10L+ installs — captured during research	Primary listing for this analysis. Record the capture date and locale with the metric.
Driver onboarding app	3.6/5 observed during research (October 10 2026)	A separate app and user journey; review it independently.
Workplace app	3.4/5 observed during research (October 11 2026)	A separate product listing; do not combine its reviews with the employee app.
G2 enterprise reviews	4.5/5 observed during research (October 11 2026)	Enterprise buyer feedback is a different audience and should not be directly compared as if it were the same sample.

Key interpretation

- The employee app's displayed 4.6/5 rating is not, by itself, proof that the rating is poor or declining.
- Recent low-star reviews can still expose specific failures that the overall average hides.
- Ratings for different MoveInSync apps should remain separate because their users and tasks differ.
- A downward trend should only be claimed after comparing dated snapshots or review-level data over time.

Questions this analysis aims to answer

- Which parts of the commute journey appear most frustrating in public feedback?
- Which complaints could cause missed rides, late arrivals or loss of trust?
- What should the team validate first, and how should success be measured?

Working principle: public reviews are a source of user-reported symptoms. They help generate hypotheses; application logs, support-ticket volumes, reproduction steps and product analytics are needed to confirm technical root causes.

2. Methodology — How the Data Was Reviewed

I used a manual, desk-research approach focused on publicly accessible sources. The aim was to understand the user journey described in reviews and compare those reports with publicly available product/support information.

Research sequence

Step	What I checked	How it was used
1. App listing	MoveInSync employee app listing and developer portfolio on Google Play	Recorded the rating and review-count snapshot visible during research; distinguished separate app listings.
2. Review reading	Public Play Store feedback and an app-review mirror such as AppBrain	Looked for recurring descriptions of login, booking, pickup and app stability problems.
3. Support context	MoveInSync Help Centre articles related to mobile app issues	Used as context for possible support pain points, not as proof of issue frequency.
4. Enterprise context	Public G2 and Capterra review pages	Considered enterprise feedback separately from employee app reviews.
5. Issue grouping	Manual tagging of review themes	Grouped complaints by user impact and the need for follow-up validation.

Issue categories used

- Login and authentication — OTP delivery, sign-in and session problems.
- Booking and confirmation — selected date/time, booking status and vehicle selection.
- Pickup and notifications — ETA, check-in reminders and no-show concerns.
- Stability and connectivity — crashes, loading and access to trip details.
- Usability and support — confusing screens, unclear instructions and difficulty getting help.

Limitations

- This is qualitative desk research, not a statistically representative survey.
- This analysis did not collect a complete, reproducible spreadsheet of every review, direct review URLs and a verified sample count.
- A support article indicates that a problem is recognised, but does not establish that it is the most frequent support issue.
- Review text alone cannot prove the underlying cause of a bug or establish a causal link between ratings of separate apps.

For these reasons, the findings below are framed as reported symptoms and hypotheses to test. Before using exact frequency claims, I would build a dated review sheet with the review text, star rating, app listing, URL and assigned category.

3. Main Themes and Root-Cause Hypotheses

Public reviews collected for this analysis highlight several problems around time-critical parts of the commute journey. The recommendations below should be treated as investigation priorities rather than confirmed engineering diagnoses.

A. Login and OTP friction

Reported symptom: some users describe difficulty receiving or entering a one-time password, or trouble completing sign-in.

Why it matters: if employees cannot access the app, they may be unable to check or manage their commute. This is a high-impact failure even if it affects only a subset of users.

Hypotheses to validate: OTP delivery delays, an overlay or screen-layout conflict, expired codes, session handling or device-specific behaviour. The review text alone does not establish which cause is responsible.

What to do: segment authentication failures by app version, Android version, device manufacturer and OTP channel; reproduce the reported flow; add clear retry and recovery states.

B. Booking date and confirmation clarity

Reported symptom: a reviewed Play Store comment describes a complaint about a booking appearing on a different date than expected, with a reported no-show consequence.

Why it matters: a wrong booking date or ambiguous confirmation can affect attendance, trust and potentially employee costs.

Hypotheses to validate: date/time selection state, timezone handling, stale UI state or a confirmation screen that does not clearly summarise the selected trip.

What to do: display the full date, pickup time and pickup point before submission; make the final confirmation explicit; log the selected values and saved booking values so discrepancies can be investigated.

C. Vehicle list and booking-state confusion

Reported symptom: reviewed feedback describes confusion after a multi-step booking flow, including uncertainty about which vehicle was booked.

Why it matters: users should be able to tell whether the booking succeeded and what action, if any, remains.

What to do: show one clear confirmation state with the booked vehicle and trip details; separate available vehicles from the vehicle already assigned to the user; test cancellation, retry and double-tap cases.

D. Pickup alerts and check-in timing

Reported symptom: reviewed feedback describes concerns about notifications arriving too late for pickup/check-in.

Why it matters: a missed or delayed alert can turn a routine commute into a missed pickup or a disputed no-show.

What to do: inspect notification delivery and timing across supported Android versions, verify permission states and compare scheduled/actual notification times with vehicle arrival data.

E. App crashes or repeated reinstallation

Reported symptom: one reviewed comment describes repeated crashes that reportedly require reinstalling the app.

Why it matters: repeated instability reduces confidence in the app, particularly when users need it at a fixed time.

Hypotheses to validate: session expiry, corrupted local state, memory pressure or a version/device-specific crash. A recurring interval alone is not enough to identify the cause.

What to do: confirm crash reporting coverage, capture stack traces and device/app-version details, and test sign-out/sign-in and long-session scenarios.

F. Trip details when connectivity is weak

Reported symptom: reviewed feedback describes difficulty viewing trip details when the phone has poor or no network connectivity.

Why it matters: pickup details may be needed in transit or at the pickup point, where connectivity can be unreliable.

What to do: assess the feasibility of securely caching the latest confirmed trip details, display a last-updated timestamp and clearly distinguish cached data from live status. Sensitive information should be stored and cleared safely.

G. Driver onboarding as a separate investigation

Research for this assignment noted a lower rating for the driver onboarding app. That is worth investigating on its own because onboarding friction may affect driver operations. However, the public data reviewed here is not enough to prove that the driver app rating directly causes a lower employee app rating.

What to do: sample recent low-star driver-app reviews separately and compare themes with operational metrics such as driver onboarding completion, cancellation rates and late pickups.

Summary of evidence strength

Finding	Evidence level	Next validation step
Users report login/OTP friction	User-reported symptom	Review authentication failure logs and reproduce cases.
Booking date/confirmation may be unclear	User-reported symptom; impact needs validation	Compare UI-selected and server-saved booking details.
Pickup alerts may arrive late	User-reported symptom	Compare notification delivery timestamps with ETA/arrival events.
Session token or overlay is the exact technical cause	Unconfirmed hypothesis	Do not implement a narrow fix until reproduced.
Driver-app rating causes employee-app rating decline	Unproven causal hypothesis	Test against operations data and review timelines.

4. Recommended Action Plan

I would prioritise by user harm, how time-critical the workflow is, the strength of evidence and the effort required to validate a fix. The first step is to reproduce and measure the issue—not to assume a particular code change is already known.

Priority	Action	Owner(s)	Success measure
P0 — Validate first	Audit login/OTP failures; reproduce top reported cases; add clear recovery messaging. Day 1: Pull the last 7 days of authentication failure logs filtered by OTP non-delivery; sort by Android version and device manufacturer to find the highest-frequency failure pattern.	Mobile engineering + QA + support	Authentication success rate; OTP delivery/verification failures; support contacts per 1,000 logins.
P0 — Validate first	Add a clear booking summary before submission and verify date/time consistency end-to-end. Day 1: Open the booking flow on three different devices and screenshot the confirmation screen — check whether the full date, time and pickup point are visible before the user taps confirm.	Product + mobile/backend engineering + QA	Booking correction reports; date/time mismatch rate; booking completion rate.
P1 — Next	Clarify booking success state and show the user's confirmed vehicle and trip details.	Product design + mobile engineering	Repeat taps, duplicate bookings, booking-related complaints.
P1 — Next	Audit pickup/check-in notifications and measure delivery latency across devices.	Mobile + platform/backend teams	Notification delivery latency; missed-pickup complaints; no-show disputes.
P1 — Next	Improve crash diagnostics and investigate repeated-crash reports.	Mobile engineering + QA	Crash-free sessions; crash rate by app version/device.
P2 — Plan after validation	Evaluate safe offline access to the latest confirmed trip details.	Product + mobile engineering + security	Trip-detail load success under weak connectivity; stale-data incidents.

Parallel track	Review the driver onboarding app as a separate workstream.	Driver product + operations + QA	Onboarding completion; failure rate by step; driver-app complaint themes.

Suggested 30-day sequence

- Week 1 — Build the review log, verify the sample, reproduce the top reported issues and establish baseline metrics.
- Week 2 — Ship small, testable fixes for confirmed P0 issues; add regression tests for login and booking.
- Week 3 — Validate pickup notification behaviour and crash diagnostics; review support tickets with engineering.
- Week 4 — Compare metrics before and after release, read new reviews and decide what should enter the next sprint.

Release discipline: use a staged rollout where possible, monitor crash and booking metrics, and keep a rollback plan for changes to critical commute flows.

5. Measuring Progress and Monitoring Ratings

A rating target should not be set in isolation. The lifetime Play Store score changes slowly and may be calculated using a weighting method that is not fully visible to an external researcher. I would focus first on reducing the problems that cause negative experiences, then use rating movement as one of several outcome measures.

Weekly monitoring

Metric	Cadence	Why it matters
Current rating and total review count, captured with date/locale	Weekly	Provides a consistent trend snapshot.
New 1–2 star reviews and their themes	Weekly	Highlights fresh pain points and possible regressions.
Authentication success and OTP failure rate	Daily/weekly	Measures whether users can enter the app.
Booking completion and date/time mismatch rate	Daily/weekly	Measures reliability in a high-impact workflow.
Pickup notification delivery latency and missed-pickup complaints	Weekly	Connects notification behaviour with user outcomes.
Crash-free sessions by app version	Daily/weekly	Helps detect regressions after releases.
Time to respond to low-star reviews	Weekly	Keeps feedback acknowledged and creates a support loop.

To make this repeatable: I would build a simple weekly tracker — a spreadsheet that records the rating, review count, date and locale each week, tags new 1–2 star reviews by issue category, and flags any week-on-week drop. This takes under 30 minutes to run manually each week and directly answers the question “how are our ratings this week?” without starting from scratch each time.

Review response approach

- Acknowledge the reported problem without arguing with the reviewer.
- Ask the user to contact the official support channel when account-specific details are required; do not request personal or trip-sensitive information in a public reply.
- If a fix has shipped, describe it accurately and invite the user to update the app or retry.
- Review prompts should be neutral and policy-compliant. Do not offer rewards for ratings or ask only satisfied users to review.

What I would avoid

- Do not promise a move from 4.6 to 4.85 within 30 days without a defensible forecast.
- Do not estimate the number of five-star ratings needed from the displayed average alone; the store’s rating calculation may not be a simple arithmetic average.
- Do not describe a suspected CSS, token or notification issue as the confirmed root cause until it has been reproduced.

- Do not combine ratings across separate apps or use enterprise review scores as if they were the same user sample.

6. Conclusion

The public feedback reviewed for this assignment points to a practical area of focus: make the critical commute journey predictable. Employees need to sign in, book the correct trip, understand whether it is confirmed and receive useful pickup information at the right time. A failure in one of these steps can be more consequential than a general usability inconvenience.

My recommendation is to start with an evidence-backed validation sprint. Create a traceable review dataset, connect the main complaints to product/support metrics and reproduce the highest-impact issues. Then fix confirmed problems in small releases and measure whether the underlying user outcomes improve. This approach avoids spending time on an assumed root cause and gives the team a repeatable way to connect public feedback with engineering priorities.

How I approached this and which tools I used

I reviewed publicly available sources: the Google Play Store employee app listing, the MoveInSync developer page, AppBrain, the MoveInSync Help Centre, and G2 and Capterra enterprise review pages. I read reviews manually and grouped recurring complaints by theme and user impact. I used AI assistance (Claude) to help structure the findings, draft the action plan and check the framing. All ratings and review counts are snapshots captured during research in October 2026 and should be verified before reuse. As a next step, I would build a lightweight script that pulls the AppBrain listing weekly, extracts the rating and review count, and outputs a structured summary — removing the manual capture step from the recurring process.

Appendix A — Review log template

Field	What to record
Review date / capture date	Date shown on the review and date it was collected.
App listing	Employee app, driver onboarding app or workplace app.
Star rating	Rating exactly as shown.
Review text and URL	Exact text with a direct link, where available.
Issue category	Login, booking, pickup/notification, stability, connectivity, usability, support or positive feedback.
Severity	High, medium or low, based on user impact—not star rating alone.
Evidence status	User-reported symptom, reproduced issue or confirmed root cause.
Suggested action / owner	Small next step and team responsible for validation.
